

# **SPACE TIME BLOCK CODED TRANSMIT ANTENNA DIVERSITY FOR WCDMA**

## **FIELD OF THE INVENTION**

5           This invention relates to wideband code division multiple access (WCDMA) for a communication system and more particularly to space time block coded transmit antenna diversity for WCDMA.

## **BACKGROUND OF THE INVENTION**

10           Present code division multiple access (CDMA) systems are characterized by simultaneous transmission of different data signals over a common channel by assigning each signal a unique code. This unique code is matched with a code of a selected receiver to determine the proper recipient of a data signal. These different data signals arrive at the receiver via multiple paths due to ground clutter  
15           and unpredictable signal reflection. Additive effects of these multiple data signals at the receiver may result in significant fading or variation in received signal strength. In general, this fading due to multiple data paths may be diminished by spreading the transmitted energy over a wide bandwidth. This wide bandwidth results in greatly reduced fading compared to narrow band transmission modes such as frequency division multiple access (FDMA) or time division multiple access (TDMA).

20           New standards are continually emerging for next generation wideband code division multiple access (WCDMA) communication systems as described in Provisional U.S. Patent Application No. 60/082,671, filed April 22, 1998, and incorporated herein by reference. These WCDMA systems are coherent communications systems with pilot symbol assisted channel estimation schemes. These pilot  
25           symbols are transmitted as quadrature phase shift keyed (QPSK) known data in predetermined time frames to any receivers within range. The frames may propagate in a discontinuous transmission (DTX) mode. For voice traffic, transmission of user data occurs when the user speaks, but no data symbol transmission occurs when the user is silent. Similarly for packet data, the user data may be transmitted only when packets are ready to be sent. The frames include pilot symbols as well as other

control symbols such as transmit power control (TPC) symbols and rate information (RI) symbols. These control symbols include multiple bits otherwise known as chips to distinguish them from data bits. The chip transmission time ( $T_c$ ), therefore, is equal to the symbol time rate ( $T$ ) divided by the number of chips in the symbol ( $N$ ).

5

Previous studies have shown that multiple transmit antennas may improve reception by increasing transmit diversity for narrow band communication systems. In their paper New Detection Schemes for Transmit Diversity with no Channel Estimation, Tarokh et al. describe such a transmit diversity scheme for a TDMA system. The same concept is described in A Simple Transmitter Diversity Technique for Wireless Communications by Alamouti. Tarokh et al. and Alamouti, however, fail to teach such a transmit diversity scheme for a WCDMA communication system.

Other studies have investigated open loop transmit diversity schemes such as orthogonal transmit diversity (OTD) and time switched time diversity (TSTD) for WCDMA systems. Both OTD and TSTD systems have similar performance. Both use multiple transmit antennas to provide some diversity against fading, particularly at low Doppler rates and when there are insufficient paths for the rake receiver. Both OTD and TSTD systems, however, fail to exploit the extra path diversity that is possible for open loop systems. For example, the OTD encoder circuit of FIG. 5 receives symbols  $S_1$  and  $S_2$  on lead 500 and produces output signals on leads 504 and 506 for transmission by first and second antennas, respectively. These transmitted signals are received by a despreader input circuit (FIG. 6). The input circuit receives the  $i^{th}$  of  $N$  chip signals per symbol together with noise along the  $j^{th}$  of  $L$  multiple signal paths at a time  $\tau_j$  after transmission. Both here and in the following text, noise terms are omitted for simplicity. This received signal  $r_j(i + \tau_j)$  at lead 600 is multiplied by a channel orthogonal code signal  $C_m(i + \tau_j)$  that is unique to the receiver at lead 604. Each chip signal is summed over a respective symbol time by circuit 608 and produced as first and second output signals  $R_j^1$  and  $R_j^2$  on leads 612 and 614 as in equations [1-2], respectively. Delay circuit 610 provides a one-symbol delay  $T$  so that the output signals are produced simultaneously.

$$R_j^1 = \sum_{i=0}^{N-1} r_j(i + \tau_j) = \alpha_j^1 S_1 + \alpha_j^2 S_2 \quad [1]$$

$$R_j^2 = \sum_{i=N}^{2N-1} r_j(i + \tau_j) = \alpha_j^1 S_1 - \alpha_j^2 S_2 \quad [2]$$

The OTD phase correction circuit of FIG. 7 receives the signals  $R_j^1$  and  $R_j^2$  as input signals corresponding to the  $j^{th}$  of  $L$  multiple signal paths. The phase correction circuit produces soft outputs or signal estimates  $\tilde{S}_1$  and  $\tilde{S}_2$  for symbols  $S_1$  and  $S_2$  at leads 716 and 718 as shown in equations [3-4], respectively.

$$\tilde{S}_1 = \sum_{j=1}^L (R_j^1 + R_j^2) \alpha_j^{1*} = \sum_{j=1}^L 2|\alpha_j^1|^2 S_1 \quad [3]$$

$$\tilde{S}_2 = \sum_{j=1}^L (R_j^1 - R_j^2) \alpha_j^{2*} = \sum_{j=1}^L 2|\alpha_j^2|^2 S_2 \quad [4]$$

Equations [3-4] show that the OTD method provides a single channel estimate  $\alpha$  for each path  $j$ . A similar analysis for the TSTD system yields the same result. The OTD and TSTD methods, therefore, are limited to a path diversity of  $L$ . This path diversity limitation fails to exploit the extra path diversity that is possible for open loop systems as will be explained in detail.

## SUMMARY OF THE INVENTION

These problems are resolved by a mobile communication system comprising an input circuit coupled to receive a first plurality of signals during a first time from an external source and coupled to receive a second plurality of signals during a second time from the external source. The input circuit receives each of the first and second plurality of signals along respective first and second paths. The input circuit produces a first input signal and a second input signal from the respective first and second plurality of signals. A correction circuit is coupled to receive a first estimate signal, a second estimate signal and the first and second input signals. The correction circuit produces a first symbol estimate in response to the first and second estimate signals and the first and second input signals. The correction

circuit produces a second symbol estimate in response to the first and second estimate signals and the first and second input signals.

The present invention improves reception by providing at least  $2L$  diversity over time and space. No additional transmit power or bandwidth is required. Power is balanced across multiple antennas.

## BRIEF DESCRIPTION OF THE DRAWINGS

A more complete understanding of the invention may be gained by reading the subsequent detailed description with reference to the drawings wherein:

FIG. 1 is a simplified block diagram of a typical transmitter using Space Time Transit Diversity (STTD) of the present invention;

FIG. 2 is a block diagram showing signal flow in an STTD encoder of the present invention that may be used with the transmitter of FIG. 1;

FIG. 3 is a schematic diagram of a phase correction circuit of the present invention that may be used with a receiver;

FIG. 4A is a simulation showing STTD performance compared to Time Switched Time Diversity (TSTD) for a vehicular rate of 3 kmph;

FIG. 4B is a simulation showing STTD performance compared to TSTD for a vehicular rate of 120 kmph;

FIG. 5 is a block diagram showing signal flow in an OTD encoder of the prior art;

FIG. 6 is a block diagram of a despreader input circuit of the prior art; and

FIG. 7 is a schematic diagram of a phase correction circuit of the prior art.

## DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Referring to FIG. 1, there is a simplified block diagram of a typical transmitter using Space Time Transit Diversity (STTD) of the present invention. The transmitter circuit receives pilot symbols,

TPC symbols, RI symbols and data symbols on leads 100, 102, 104 and 106, respectively. Each of the symbols is encoded by a respective STTD encoder as will be explained in detail. Each STTD encoder produces two output signals that are applied to multiplex circuit 120. The multiplex circuit 120 produces each encoded symbol in a respective symbol time of a frame. Thus, a serial sequence of symbols in each frame is simultaneously applied to each respective multiplier circuit 124 and 126. A channel orthogonal code  $C_m$  is multiplied by each symbol to provide a unique signal for a designated receiver. The STTD encoded frames are then applied to antennas 128 and 130 for transmission.

Turning now to FIG. 2, there is a block diagram showing signal flow in an STTD encoder of the present invention that may be used with the transmitter of FIG. 1. The STTD encoder receives symbol  $S_1$  at symbol time  $T$  and symbol  $S_2$  at symbol time  $2T$  on lead 200. The STTD encoder produces symbol  $S_1$  on lead 204 and symbol  $-S_2^*$  on lead 206 at symbol time  $T$ , where the asterisk indicates a complex conjugate operation. Furthermore, the symbol time indicates a relative position within a transmit frame and not an absolute time. The STTD encoder then produces symbol  $S_1$  on lead 204 and symbol  $S_1^*$  on lead 206 at symbol time  $2T$ . The bit or chip signals of these symbols are transmitted serially along respective paths 208 and 210. Rayleigh fading parameters are determined from channel estimates of pilot symbols transmitted from respective antennas at leads 204 and 208. For simplicity of analysis, a Rayleigh fading parameter  $\alpha_j^1$  is assumed for a signal transmitted from the first antenna 204 along the  $j^{\text{th}}$  path. Likewise, a Rayleigh fading parameter  $\alpha_j^2$  is assumed for a signal transmitted from the second antenna 206 along the  $j^{\text{th}}$  path. Each  $i^{\text{th}}$  chip or bit signal  $r_j(i + \tau_j)$  of a respective symbol is subsequently received at a remote mobile antenna 212 after a transmit time  $\tau_j$  corresponding to the  $j^{\text{th}}$  path. The signals propagate to a despreader input circuit (FIG. 6) where they are summed over each respective symbol time to produce output signals  $R_j^1$  and  $R_j^2$  corresponding to the  $j^{\text{th}}$  of  $L$  multiple signal paths as previously described.

Referring now to FIG. 3, there is a schematic diagram of a phase correction circuit of the present invention that may be used with a remote mobile receiver. This phase correction circuit

receives signals  $R_j^1$  and  $R_j^2$  as input signals on leads 610 and 614 as shown in equations [5-6], respectively.

$$R_j^1 = \sum_{i=0}^{N-1} r_j(i + \tau_j) = \alpha_j^1 S_1 - \alpha_j^2 S_2^* \quad [5]$$

$$R_j^2 = \sum_{i=N}^{2N-1} r_j(i + \tau_j) = \alpha_j^1 S_1 + \alpha_j^2 S_1^* \quad [6]$$

5 The phase correction circuit receives a complex conjugate of a channel estimate of a Rayleigh fading parameter  $\alpha_j^{1*}$  corresponding to the first antenna on lead 302 and a channel estimate of another Rayleigh fading parameter  $\alpha_j^2$  corresponding to the second antenna on lead 306. Complex conjugates of the input signals are produced by circuits 308 and 330 at leads 310 and 322, respectively. These input signals and their complex conjugates are multiplied by Rayleigh fading parameter estimate signals  
10 and summed as indicated to produce path-specific first and second symbol estimates at respective output leads 318 and 322 as in equations [7-8].

$$R_j^1 \alpha_j^{1*} + R_j^{2*} \alpha_j^2 = (|\alpha_j^1|^2 + |\alpha_j^2|^2) S_1 \quad [7]$$

$$-R_j^{1*} \alpha_j^2 + R_j^2 \alpha_j^{1*} = (|\alpha_j^1|^2 + |\alpha_j^2|^2) S_2 \quad [8]$$

These path-specific symbol estimates are then applied to a rake combiner circuit to sum individual path-specific symbol estimates, thereby providing net soft symbols as in equations [9-10].  
15

$$\bar{S}_1 = \sum_{j=1}^L R_j^1 \alpha_j^{1*} + R_j^{2*} \alpha_j^2 \quad [9]$$

$$\bar{S}_2 = \sum_{j=1}^L -R_j^{1*} \alpha_j^2 + R_j^2 \alpha_j^{1*} \quad [10]$$

These soft symbols or estimates provide a path diversity  $L$  and a transmit diversity 2. Thus, the total diversity of the STTD system is  $2L$ . This increased diversity is highly advantageous in providing a reduced bit error rate. The simulation result of FIG. 4 compares a bit error rate (BER) of STTD with  
20 TSTD for various ratios of energy per bit ( $E_b$ ) to noise ( $N_0$ ) at a relative speed of 3 Km/h. The OTD and TSTD systems were found to be the same in other simulations. The simulation shows that a 7.5 dB ratio  $E_b/N_0$  corresponds to a BER of  $2.0 \times 10^{-3}$  for TSTD. The same BER, however, is achieved with a

7.2 dB ratio  $E_b/N_0$ . Thus, STTD produces approximately 0.3 dB improvement over TSTD. The simulation of FIG. 5 compares the BER of STTD with TSTD for various values of  $E_b/N_0$  at a relative speed of 120 Km/h. This simulation shows a typical 0.25 dB improvement for STTD over TSTD even for high Doppler rates. By way of comparison, STTD demonstrates a 1.0 dB advantage over the simulated curve of FIG. 5 without diversity at a BER of  $2.6E-3$ . This substantial advantage further demonstrates the effectiveness of the present invention.

Although the invention has been described in detail with reference to its preferred embodiment, it is to be understood that this description is by way of example only and is not to be construed in a limiting sense. For example, several variations in the order of symbol transmission would provide the same  $2L$  diversity. Moreover, the exemplary diversity of the present invention may be increased with a greater number of transmit or receive antennas. Furthermore, novel concepts of the present invention are not limited to exemplary circuitry, but may also be realized by digital signal processing as will be appreciated by those of ordinary skill in the art with access to the instant specification.

It is to be further understood that numerous changes in the details of the embodiments of the invention will be apparent to persons of ordinary skill in the art having reference to this description. It is contemplated that such changes and additional embodiments are within the spirit and true scope of the invention as claimed below.
